

Project name: AssistQ

Prepared by: Ziad Ahmed Fawzy

Objective: organize, prioritize, trust Client and quality call

Problem:

When I receive a call, sometimes I need to check or know something, so I say "Please, wait a few moments and I will be back", and here the "Wizard" goes to check or answer me in this case, and at the same time the person needs an answer to his status and here the problem appears that sometimes he leaves me and goes to see the status of this person and the time on hold for the customer increases and I go and say a few moments again on hold and at this moment I lose the customer's trust and waste more and more time making the quality of the call the worst thing and finally we are losing money when client says "i will delete all Account and i will transfer all line another company".

Issue:

- Lose trust of Customer
 - Increase waiting time
 - Chaos in floor
 - wasting time
 - reduce quality of call
 - A wizard never knows when an agent needs him.
 - There may be incorrect information from the wizard due to multiple cases.
-

Solution:

Makes a strong system to organize the queue (FIFO) of requests and organizes the motion of the agent and wizard on the system; that is, it makes an organization on the floor.

What next?

I have created a system to organize Requests and distribute orders in an orderly manner on Wizard

How It Works:

- Open the AssistQ and Login (username, password)
- Display smooth and clearly user interface
- When I have any Question/problem within the call I will make request
- Input Reason (dropdown) and priority (dropdown)
- Push request
- Wizard is receiving the Request (name, reason, priority) and going to Agent to solve request
- Solving the issue and push solve and agent make shaking hand
- The process is repeated in this manner.

Features:

- secure from XSS (cross site scripting)
- secure from request injection attack (crashed server)
- secure from invalid inputs
- using tokens (JWT, bcrypt) to encryption
- recover page process
- high and clearly performance UI & UX design
- middleware to authorization & authentication
- API key for security
- prevent overload on server
- Makes real time System

Future Features:

- Time to complete any case
- Notification on mobile App
- Record and Analysis performance

- Completely Dashboard with full control from (Admin / supervisor)

Tech Stack Proposal

- Frontend: React
- Backend: Node.js / Express
- Database: MongoDB / JSON file for MVP (I can use SQL)
- Real-time: WebSocket or Firebase

Thanks for reading.
